Humic Substances in Ecosystems 8, Šoporňa 13.-17.9.2009 Slovakia

# Introduction

Multicomponent analysis of ionogenic compounds complex environmental (humic substances, etc.) or biological matrices (biopolymers, low MW substances) is in many aspects still **problematic**, especially from the point-of-view of refined requirements of praxis.

Systematic combination of various separation principles and/or **column separation methods** hyphenation offers many attractive features of **manipulation with selectivity of separation and detection** and **speed of analysis**

Relation of sample complexity and theory of peak overlap in separation systems.

**No one** current single analytical method can resolve all components of complex natural or technological samples as follows from

Davis and Giddings statistical peak overlap theory based on homogeneous statistics

Davis J.M., Giddings J.C.: *Anal.Chem.*, 55 (1983) 418.

J.M.Davis: *Anal.Chem.*, 69 (1997) 3796.

## What does it mean complex sample?

Each sample is complex at certain – usually low concentration level of its components when number of sample components exceeds component capacity of given separation or detection method. Soil column chromatography.

(even highly purified water or rain water are complex samples at ppt and lower levels).

## RP-HPLC profiles of Peat Humic Acid on 30 nm pore diameter C18 column

Note: similar profiles are typical for almost all analytical methods

## Basic aspects of combination of liquid chromatography methods or alternative methods

For real sample pretreatment and multicomponent (**trace**) analysis we should achieve whenever possible

- **high selectivity** of redistribution (HPLC-variable modes) and detection
- **high efficiency** of transport phenomena (quantitative) and detection yield (sensitive, low LOD, LOQ)
- **high enrichment** ( $10^2$ - $10^6$ ) and **pre-concentration factors** achievable in **gradient and column switching HPLC**
- **quantitative transfer** of sample within analytical procedure and/or method
- **accurate results**
- **short analysis** duration (fast and ultrafast LC 1-10 min)
- **low cost** of analysis

This is practically impossible without complex and complicated analytical procedure schema, smart and expensive instrumentation and consistent analyses quality control.

Definite effort is given to elaboration of robust, validated and universally applicable analytical methods based also on HPLC.

In spite of fact that  
system of quality assurance and quality control  
suffers from

lack of proper certified HSs standard reference materials  
referring to certain exact locality

for validation of both existing and new analytical methods

# COMBINATION OF SEPARATION TECHNIQUES FOR ANALYSIS OF IONOGENIC SUBSTANCES IN COMPLEX MATRICES

**Complexity of problems** associated with **trace or ultratrace analysis (ppb to ppt)** of substances in a natural matrices is reflected mainly by the fact that

for their successful solution **we need to combine or hyphenate even highly efficient techniques.** Beside on-line coupled separation and identification or detection methods, e.g., HPLC-MS etc., possibilities of combinations and hyphenation of separation methods is intensively investigated and researched.

This originates so called **two- or multi-dimensional separation techniques**, e.g. HPLC-HPLC or ITP-CZE and the other.

These methods are according to their principles applicable for distinct groups of substances having differing numbers of entities.

**By the combination of analytical methods we can according to the nature of problem and aim of the problem solution achieve that number of analysed substances:**

- **increases** for methods complementary each other (some LC-LC methods, e.g. SEC- RPLC)
- **stays unchanged**, but the combination enables better characterization of sample and/or identification ability of sample components (e.g. PyGC-MS, IEX-RPLC-MS etc.) by increase of information content of analysis,
- **decreases** when such methods are combined, that first method has narrower applicability than the second one, but their combination gives higher discrimination ability.

# CONCEPTS OF METHODS AND TECHNIQUES COMBINATION

Systematic change of selectivity during separation process enables us to attain practically not restricted separation possibilities under the condition that we are not restricted by available time.

Advantages of successive (tandem) use of various separation modes (mode sequencing) we can express mathematically. According to Giddings is **peak capacity of simple isocratic mode  $\phi$**  given by equation:

$$\phi = 1 + (N^{1/2} / m) \cdot \ln(1 + k'_n)$$

where for unity resolution  $m = 4$  (4  $\sigma$  separation),  
 $N$  = plate number,  
 $k'_n$  = retention factor of last peak

in a series of peaks numbered from zero (nonretained) to  $n$  (last detectable peak).

- Peak capacity  $\phi$  is based on determination of maximal number of solutes (peaks), that can be resolved with unity resolution  $R_s = 1$  in a given system and within certain time interval

## Peak capacity $\phi$

HPLC gradient elution	200 - 300
HPLC isocratic elution	cca 50
SEC isocratic elution	3-10
CZE	200 - 800
ITP	cca 100
IEF	200 - 300

If peak capacity of all n modes is equal, we get:

$$\phi_T = \phi^n$$

Requirement of **non-redundancy**, or **non-correlation** and **orthogonality** between individual combined modes is the main requirement and at the same time also assumption or premise of the relation

$$\phi_T = \phi^n$$

because on contrary

Combination of **n** equal modes (identical columns) in a series increases **overall efficiency** according to equation:

$$\phi_T = 1 + [(nN)^{1/2} / m] \cdot \ln(1 + k_n)$$

what is approximately equal to

$$\phi_T \sim n^{1/2} \cdot \phi_i$$

## Requirement of non-redundancy, or non-correlation and orthogonality

Orthogonality of separations or detection is a discussed philosophy of multi-dimensional system design.

Orthogonal design means that features multiply each other's utility, and overlap as little as possible.

Given set of carefully-crafted orthogonal features can enable a wide variety of possibilities for complex analysis through combining those features.

In theory, this means that one can have a small and simple instrumental base, which enables an extremely rich methodological environment for chemical analysis.

## The highest separation efficiency is achieved by discrete combination of selective methods.

For proper selection of the most effective combinations we should take into account that correlation of the data **is not given only by physico-chemical principle of combined methods, but also by a sample itself**

- **chemical structure of components**
- **number of sample components**

and favorites proper choice of

differently selective – focused to dissimilar sample properties,  
high performance and  
very compatible separation processes.

Multicolumn switching Liquid Chromatography

Liquid Chromatography and Capillary Electrophoresis

Criteria for selection of methods suitable for combining in analytical separation schema applied to methods of liquid chromatography and capillary electrophoresis

**Efficiency, Selectivity, Compatibility**  
considerations

**HPLC**

**Efficiency 1000 to 10000** plates per column. Exceptionally 1 - 2 orders of magnitude higher

**Peak capacity** – for common standard columns (250mm/4mm,3-5 $\mu$ m) isocratic **50-100**, gradient **250-300**, SEC **5 to 20**

**CZE**

**Efficiency 5000 to 500 000**, **peak capacity 300 - 500** for low molecular weight substances and **500 to 800** for polymeric substances.

**ITP**

peak capacity equivalent - "**zone capacity**" is estimated to **50 - 100** .

## Discrete vs continual

In principle we can combine two methods as

- discrete methods, 2D separation then exploit greater separation space in which every and each sample component has its own exact coordinates
- continual methods, 2D separation requires instant presence of both separation mechanisms and movement of separated components we can imagine as trajectories of points in 2D space, what restricts available separation space (2 D Planar LC, CEC, MEKC)

## Coupling and Interfacing

Four levels of coupling can be distinguished :

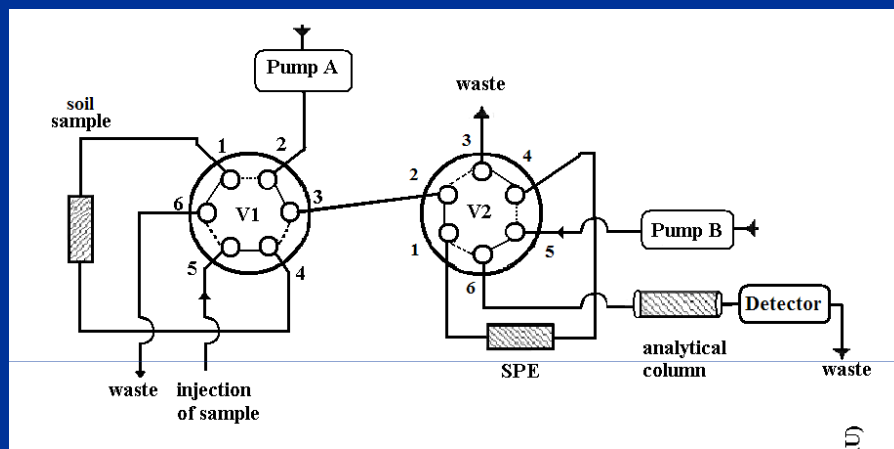

- ❖ **off-line** (manual),
- ❖ **at-line** (robotic interface)
- ❖ **on-line** (coupling via a transfer line)
- ❖ **in-line** (complete integration including sample preparation)

Heart-cutting (non-comprehensive) or comprehensive sampling from first to second step or dimension
